The Ignitor High Speed Pellet Injector* F. BOMBARDA, S. MIGLIORI, A. FRATTOLILLO, ENEA, Italy, L.R. BAYLOR, J.B.O. CAUGHMAN, S.K. COMBS, D. FEHLING, C. FOUST, J.M. MCJILL, ORNL, G. ROVETA, CRIOTEC Impianti, Italy — A joint ENEA-Frascati and ORNL program for the development of a four barrel, two-stage pellet injector for the Ignitor experiment is in progress. The pellets will reach velocities up to 4 km/s, in order to penetrate close to the center of the plasma column when injected from the low field side at the temperatures expected at ignition. Recent activities carried out at ORNL include improvements to the cryostat, the addition of miniature adjustable heaters in the the freezing zone, and of four close-coupled valves for rapid evacuation of gas after a shot. The LabView application software was successfully used to control the simultaneous formation of D$_2$ pellets, from 2.1 to 4.6 mm in diameter, that were launched at low speed. ORNL developed, specifically for this application, the light gate and microwave cavity mass detector diagnostics that provide in-flight measurements of the pellet mass and speed, together with its picture. The ENEA two-stage pneumatic propelling system, now ready for shipping to ORNL, makes use of special pulse shaping valves, while fast valves in the independent gas removal lines prevent the propulsion gas from reaching the plasma chamber. Novel experiments, e.g. to create high pressure plasmas in existing devices using this innovative facility, have been envisioned and are being simulated.

*Sponsored in part by ENEA of Italy and by the U.S. D.O.E.

The Ignitor Experiment

Ignition can reach ignition shortly after the end of the current ramp (-4 sec) when Ohmic heating only is present, with central density of \(n_c = 10^{20} \text{ m}^{-3}\), peak temperature of \(T_{\text{e}} \approx 11 \text{ keV}\), \(T_{\text{p}} = 13 \text{ keV}\) and \(I_c = 11 \text{ MA}\).

During the current rise, it is particularly important to tailor the density profile peaking to obtain an optimal rate of Ohmic and fusion heating.

In Ignitor, pellet injection can be more effectively done from the Low Field Side. To yield significant effects, injected pellets must penetrate near the center of the plasma column.

Pellet Penetration

An analysis of deuterium pellet penetration for Ignitor was carried out using the NGS simulation code1 for the pellet sizes that the IFI is capable of producing. Plasma temperatures and densities were described by parameterized profiles, with central values ranging from 1 to 13 keV for the temperature, and 0.5 to 12.5 \(10^{20} \text{ m}^{-3}\) for the density.

Thanks to the compact size of the machine, it was found that pellets of 4 mm at 4 km/s can reach the central part of the plasma column for the typical plasma parameters found at or near ignition conditions. At the lower parameters, smaller and slower pellets can be used.

Penetration of 4 mm pellets in Ignitor

Ablation Depth of \(D_2\) pellets into LHD

A similar analysis has been applied to plasma produced by the Large Helical Device. This is a superconducting, large aspect ratio plasma major radius \(M = 3.8 \text{ m}\), minor radius \(a = 0.6 \text{ m}\), suitably shaped helical machine, where remarkably high densities \(\sim 5 \times 10^{20} \text{ m}^{-3}\) plasma have been obtained with pellet injection in the presence of a Local Island Domino (LID). These plasmas, well confined, but relatively cold \(\sim 1 \text{ keV}\) plasma regimes have the potential of leading to new ignition scenarios provided that higher temperatures (of the order of 10 keV) are achieved. The estimated maximum penetration depth in LHD for a 5 mm pellet \(10^7 \text{ D mm}^{-1}\) is shown as a function of increasing electron temperature, for a fixed peak density \(n_p = 5 \times 10^{20} \text{ m}^{-3}\) and different velocities. At the highest speed, the pellet can penetrate inside the internal Diffusion Barrier (approximately located at \(\rho = 0.35\)) even at the highest temperatures, possibly raising the density by \(2 \times 10^7 \text{ part/m}^3\).

Ablation depth of deuterium pellets in LHD. Pellet injection rate is \(10^7 \text{ pellets per second}\) and peak density \(5 \times 10^{20} \text{ m}^{-3}\). Density and energy confinement profiles are assumed to be parabolic and parabolic square, respectively.

Proceedings of the 21st IAEA FEC, Chengdu, China (October 2005)
Paper CH.3-1
A four barrel, two-stage pneumatic pellet injector for the ignitor experiment is under construction in collaboration between the ENEA Laboratory at Frascati and Oak Ridge National Laboratory. The goal is to reach pellet velocities of about 4 km/s, capable of penetrating near the center of the plasma column when injected from the low field side.

The innovative concepts at the basis of the ignitor pellet injector (IPI) design are the proper shaping of the propellant gas pressure from its storage ball to improve pellet acceleration, and the use of fast valves to considerably reduce the expansion volumes which prevent the propellant gas from reaching the plasma chamber.

### The ENEA sub-system

The ENEA sub-system includes the pneumatic propelling system (4 TSGs and 4 PSVs), the gas removal system (4 independent lines) and related diagnostics as well as its own control and data acquisition system (C&HAS). The C&HAS has been improved to allow control and data acquisition on two distinct computers, and to provide easier and more immediate access to mimics and data. An additional cut-off (pneumatically actuated) ball valve has been integrated in the valve body to separate the pneumatic guns from the launching barrel. This allows to disassemble each TSG from the cryostat without breaking the vacuum in the launching barrel and to ignore possible small leakages through the PSV. Further tests have been carried out to characterize the gas removal system.

### The ORNL sub-system

The ORNL sub-system consists of the cryostat and pellet diagnostics, as well as of its own C&HAS. The assembly of most of its components was recently completed, and testing with D₂ pellets was started, using standard ORNL propellant valves.

The IPI consists of four independent injection lines, each including a two-stage pneumatic gun (TSG), a pulse shaping relief valve (PSV), a pneumatic gas removal line, and related diagnostics, sharing a single cryostat, a common pellet mass probe, and an accelerometer target.

Italian patent and trademark Office, Rec. No. RM354000100, issued on Feb 30, 1991

Two independent sub-systems have been built by ENEA and ORNL separately.

---

The ENEA and ORNL systems are ready to be integrated for testing the complete system at high pellet speeds. A wide range of operating parameters will be explored.
